

# Follow

## Motivation

- ▶ Consider top down parsing
- ▶ We are at a node representing nonterminal  $X$
- ▶ Need to decide which production to expand  $X$  into
- ▶ But we also need to know when we're *done* with  $X$

## Follow

- ▶ Example: How do we know when we are done parsing a given expansion?
- ▶  $\text{stmt} \rightarrow \text{assign} \mid \text{if-stmt}$   
 $\text{assign} \rightarrow \text{ID} = \text{expr}$   
 $\text{if-stmt} \rightarrow \text{IF expr stmt}$   
 $\text{expr} \rightarrow \text{NUM expr'}$   
 $\text{expr'} \rightarrow + \text{NUM expr'} \mid \lambda$
- ▶ Suppose we have these tokens:  
if 5 + 3 + 2 a=3
- ▶ How will parser know where expr ends and stmt begins?
  - ▶ Easy for a human to do, but we want an automated approach

## Definition

- ▶ Def:  $\text{follow}[X]$ : Set of all tokens that can appear in input immediately after that part that corresponds to expansion of  $X$ .
  - ▶ I.e., they are the tokens that can *follow* an expansion of  $X$
  - ▶ Note: Terminals have no entries in  $\text{follow}[]$  because they are never expanded
- ▶ Idea: If we are doing expansion for nonterminal  $N$  and we need to decide if we're done, see if next token is in  $\text{follow}[N]$ .
- ▶ If so: We are done with  $N$ .

## Example

- ▶  $S \rightarrow A x \mid B y$   
 $A \rightarrow a \mid b$   
 $B \rightarrow c \mid d$
- ▶  $\text{Follow}[A] = \{x\}$ 
  - ▶ Why? Because any time we have an A, must be followed with an x when expansion done
- ▶  $\text{Follow}[B] = \{y\}$ 
  - ▶ Same reason
- ▶  $\text{Follow}[S] = \text{end of string}$ 
  - ▶ Usually denoted with \$

## Example

- ▶  $S \rightarrow A x \mid B y$   
 $A \rightarrow A a \mid b$   
 $B \rightarrow A z \mid c$
- ▶  $\text{Follow}[A] = \{a, x, z\}$
- ▶  $\text{Follow}[B] = \{y\}$ 
  - ▶ We only care about what follows B's entire chain of derivation.
  - ▶ Ex:  $S \rightarrow \underline{B} y \rightarrow \underline{A z} y \rightarrow \underline{A a z} y \rightarrow \underline{A a a z} y \rightarrow \underline{b a a z} y$
- ▶  $\text{Follow}[S] = \{\$ \}$

## Example

- ▶  $S \rightarrow y A \mid x$   
 $A \rightarrow b b \mid c \mid A d$
- ▶  $\text{Follow}[S] = \{\$ \}$
- ▶  $\text{Follow}[A] = \{d, \$ \}$ 
  - ▶ Since A is at end of one of S's derivations, it can be followed by whatever follows S

## Example

►  $S \rightarrow A x \mid A B$

$$A \rightarrow a$$

$$B \rightarrow b \mid \lambda$$

►  $\text{Follow}[B] = \{\$ \}$

►  $\text{Follow}[S] = \{\$ \}$

►  $\text{Follow}[A] = \{x, b, \$ \}$

- Why \$? We can derive:

$$S \rightarrow \underline{A} B \rightarrow \underline{A} \rightarrow \underline{a}$$

- So the thing that A expanded into (“a”) is followed by the end of the string

## Example

- ▶  $S \rightarrow A x \mid A B \mid A B C D y \mid A B C z$
  - ▶  $A : a c b \$ w y x z d$
  - ▶  $S : \$ d$
  - ▶  $B : a c \$ w y z d$
  - ▶  $C : a c \$ w y z d$
  - ▶  $D : y \$ d$
- D
- $A \rightarrow a$
- $B \rightarrow b \mid C \mid \lambda$
- $C \rightarrow c \mid \lambda$
- $D \rightarrow S d \mid w \mid \lambda$

## Computing Follow

- ▶ When computing  $\text{first}[x]$  we only looked at productions with left hand side of  $x$
- ▶ When computing  $\text{follow}[x]$ , we must look at all productions
  - ▶ If  $x$  appears in a production: That production somehow contributes to  $\text{follow}[x]$
- ▶ Assume that nullable and first are known

# Algorithm

```
1 follow = {}
2 follow[start_symbol]=set( ["$"] )
3 do
4     for all nonterminals N:
5         for all productions P with lhs of N:
6             for i in range(len(P)):
7                 x=P[i]
8                 if x is nonterminal:
9                     for y in P[i+1:]:
10                        add first[y] to follow[x]
11                        if y not in nullable:
12                            break
13                 if we didn't break out:
14                     add follow[N] to follow[x]
15 until follow stabilizes
```

## Example

- ▶ Grammar:

$$S \rightarrow a \mid A b B \mid B C e$$
$$A \rightarrow x \mid C y$$
$$B \rightarrow C C \mid q$$
$$C \rightarrow \lambda \mid w$$

- ▶ Firsts:

$$A: w, x, y$$
$$B: q, w$$
$$C: w$$
$$S: a, e, q, w, x, y$$

- ▶ Follows:

$$A: b$$
$$B: \$, e, w$$
$$C: \$, e, w, y$$
$$S: \$$$

## Example

- Now we can go back to our example from before:

stmt  $\rightarrow$  assign |  
cond  
assign  $\rightarrow$  ID = expr'  
cond  $\rightarrow$  IF expr  
stmt  
expr  $\rightarrow$  NUM expr'  
expr'  $\rightarrow$  + NUM  
expr' |  $\lambda$

**Nullable:**  
expr'

**Firsts:**  
stmt: NUM, IF  
assign: ID  
cond: IF  
expr: NUM  
expr': +

**Follows:**

stmt: \$  
assign: \$  
cond: \$  
expr: \$, NUM, IF  
expr': \$, NUM, IF

## Parse

- ▶ Input: if 5 + 3 + 2 a=3
- ▶ Tokens: IF NUM + NUM + NUM ID = 3
- ▶ Parsing:
  - ▶ We know we're expanding start ('stmt')
  - ▶ Two alternatives
  - ▶ Only one begins with "IF" (use first to determine which one to use)
  - ▶ So we're working on cond  $\rightarrow$  IF expr stmt

## Parse

- ▶ Match the IF with the input
- ▶ Remaining input: NUM + NUM + NUM ID = 3
- ▶ We know next thing is expr
- ▶ We know that follow[expr] contains ID
- ▶ So when we reach the ID, we're done with expr and we can go back to working on the cond

# Assignment

- ▶ Extend your code to compute the follow set for a grammar
- ▶ Your program must work with the [test suite](#)
